This documentation contains general information about the package usage.
If you have any further issue or question, feel free to contact me on: zefaistos@live.com

RENDER PIPELINES
This package includes .unitypackage files for Built-in, URP and HDRP materials. Double-click the specific .unitypackage in order to extract and replace the existing materials to a different pipeline.

By default, the demo scene and materials use the Built-in pipeline.

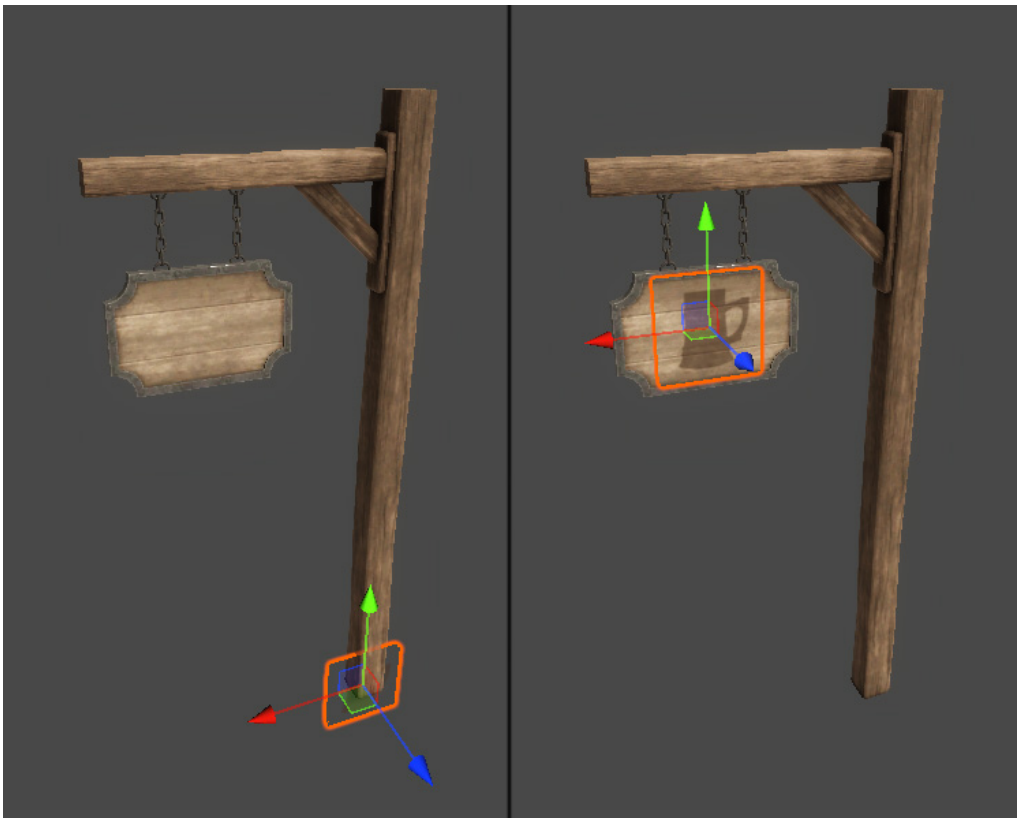
For more information about render pipelines, you can check the official documentation:
Unity - Manual: Render pipelines (unity3d.com)

TEXTURE MAPS
Most Unity built-in shaders use a texture map (Mask Map) for information such as metallic (red channel) and glossiness/smoothness (alpha channel) combined in the same texture.

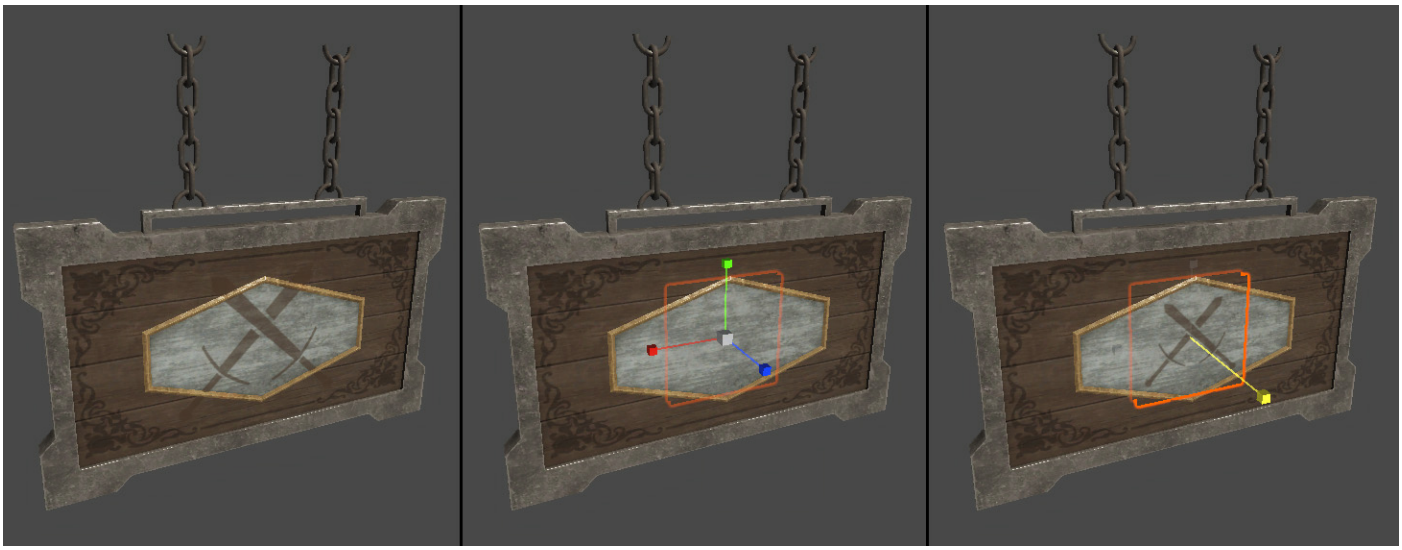
Along the Mask Map textures, metallic and roughness separate textures are also included.

SIGN SYMBOLS
The sign symbols/icons use a separate mesh and material overlaying the signs, similar to how decals work. You can find the prefabs for the sign symbols inside the Prefabs folder in their own folder.

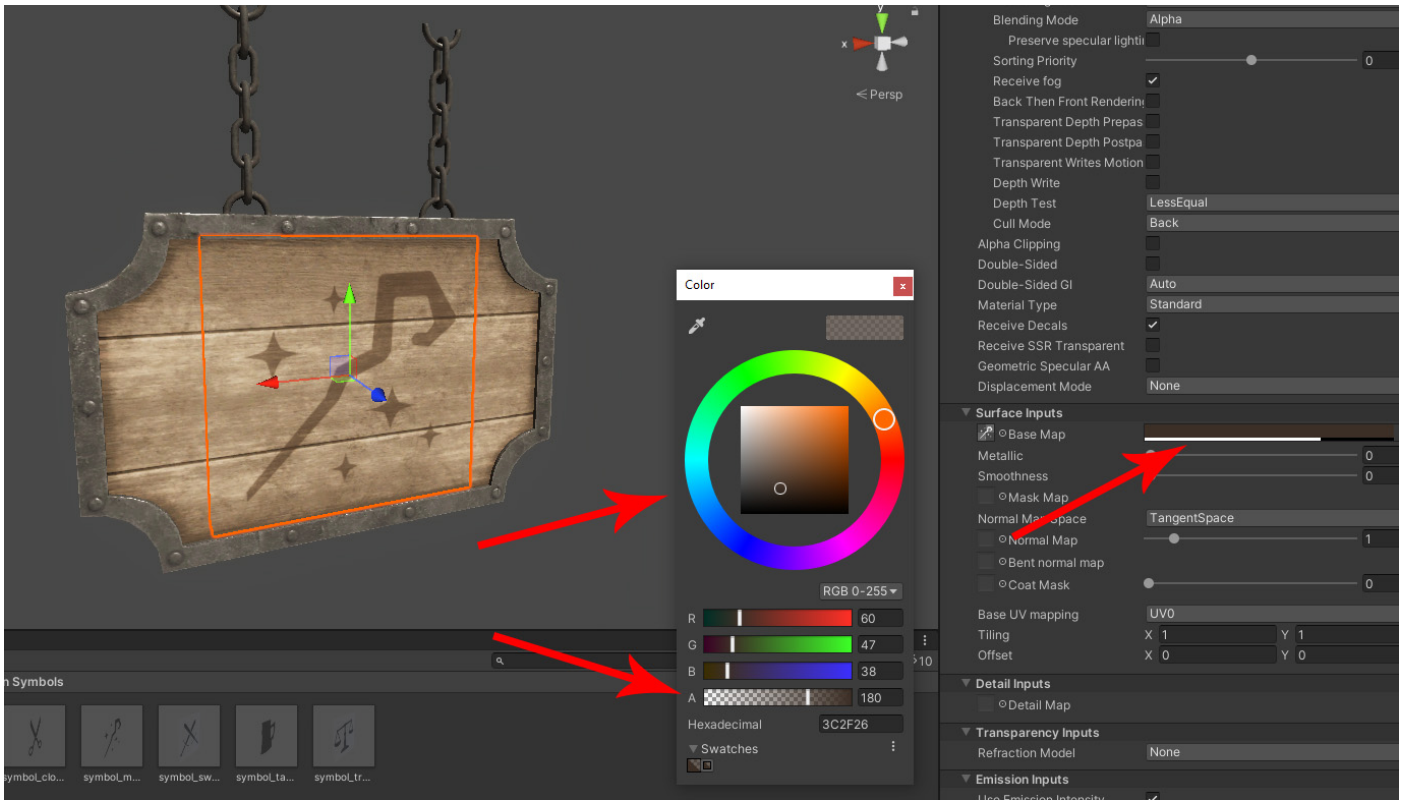
The easiest way to add a symbol/icon to a sign, is by dragging the prefab symbol to the scene, directly as a child of the sign. The symbol will spawn at the base of the sign (pivot location), and you just need to align the symbol object along the X and Y axes. The scale is already adjusted for Signs 01, 02 and 03.



For Sign 04, you need to adjust the scale of the symbol object in order to fit the central panel. In this case you can scale down the whole object, and after that scale the object along the Z axis until it's visible over the sign.



You can easily replace any of the included textures by your own custom textures. In the root location of the package you'll find the Sign Symbols folder, including all textures, materials and the base mesh used for all of the symbol prefabs. You can use this folder to store your custom sign symbol textures, so you can replace textures, or duplicate and create new materials as needed.

The recommended format is a .png texture with a transparent background.


When using textures with different colors and transparency, make sure to adjust the shader color and alpha values in order to get the results you need.
